[Designation of Document] Specification

[Title of the Invention] ARC TUBE AND MANUFACTURING METHOD

THEREFOR

[Claims]

[Claim 1] An arc tube comprising: an arc-tube body which incorporates a light-emission tube arranged to form a discharge space and having pinch seal portions formed on the two sides thereof and which is made of quartz glass; and a pair of tungsten electrodes pinch-sealed to said pinch seal portions such that the leading ends of said pair of tungsten electrodes project into said discharge space, wherein

average roughness of the surface of each of said tungsten electrodes is set to be 3 mm or smaller.

[Claim 2] A method of manufacturing an arc tube incorporating an arc-tube body which incorporates a light-emission tube arranged to form a discharge space and having pinch seal portions formed on the two sides thereof and which is made of quartz glass; and a pair of tungsten electrodes pinch-sealed to said pinch seal portions such that the leading ends of said pair of tungsten electrodes project into said discharge space, said method of manufacturing an arc tube comprising the steps of: inserting and disposing a tungsten electrode arranged such that the mean surface roughness is

3 mm or smaller into portions of a quartz glass tube in which pinch seal portions are formed; and pinch-sealing said portions in which said pinch seal portions are formed in a state where

said portions in which said pinch seal portions are formed are heated to 2000°C or higher so that each pinch seal portion is formed.

[Detailed Description of the Invention]

[0001]

[Field of the Invention]

The present invention relates to an arc tube serving as a light source, such as a headlight of a vehicle, and a manufacturing method therefor.

[0002]

[Prior Art]

In recent years, arc tubes each of which is capable of realizing a high brightness have widely been used as light sources, for example, the headlights of vehicles.

[0003]

In general, an arc tube serving as a light source, such as a headlight of a vehicle, as shown in Fig. 5, incorporates a quartz glass arc-tube body 104 having pinch seal portions 104b formed on the two sides of a light-emission tube 104a constituting a discharge space 102. Moreover, the arc tube incorporates a pair of tungsten electrodes 106 pinch-sealed to the pinch seal portions 104b such that the leading ends of the tungsten electrodes 106 project into the discharge space 102.

[0004]

The arc tube having the above-mentioned structure is arranged such that each of the tungsten electrodes 106 is

electrically polished to smooth the surface of each of the tungsten electrodes 106 to obtain a predetermined discharge characteristic.

[0005]

[Problems to be Solved by the Invention]

From a viewpoint to prevent occurrence of a leak from the arc-tube body 104, experiments conducted by the inventors of the present invention resulted in the following fact. That is, the simple electrolytic polishing process which is performed in order to maintain the discharge characteristic cannot attain a satisfactory smoothness of the surface of each of the tungsten electrodes 106.

[0006]

When the surface of each of the tungsten electrodes 106 has somewhat roughness, the tungsten electrodes 106 and the pinch seal portions 104b are engaged to each other with great pits and projections as shown in Fig. 6 after the tungsten electrodes 106 have been pinch-sealed to the pinch seal portions 104b. Therefore, excessively large compressive stress is maintained in a region adjacent to the surfaces of the pinch seal portions 104b with which the pinch seal portions 104b are joined to the tungsten electrodes 106. The large compressive stress causes a crack of the arc-tube body 104 to occur during use of the arc tube. Thus, a leak occurs between the discharge space 102 and the external space. Therefore, there arises a problem in that the life of the conventional arc tube is unsatisfactorily short.

[0007]

In view of the foregoing, an object of the present invention is to provide an arc tube which is capable of preventing occurrence of a leak caused from a crack of the arc-tube body so as to elongate the life of the arc tube and a manufacturing method therefor.

[0008]

[Means for Solving the Problem]

The present invention is arranged to improve the smoothness of the surfaces of the tungsten electrodes to achieve the foregoing object.

[0009]

That is, according to one aspect of the present invention, there is provided an arc tube comprising: an arc-tube body which incorporates a light-emission tube arranged to form a discharge space and having pinch seal portions formed on the two sides thereof and which is made of quartz glass; and a pair of tungsten electrodes pinch-sealed to the pinch seal portions such that the leading ends of the pair of tungsten electrodes project into the discharge space, wherein

average roughness of the surface of each of the tungsten electrodes is set to be 3 mm or smaller.

[0010]

According to another aspect of the present invention, there is provided a method of manufacturing an arc tube incorporating an arc-tube body which incorporates a light-emission tube arranged to form a discharge space and

having pinch seal portions formed on the two sides thereof and which is made of quartz glass; and a pair of tungsten electrodes pinch-sealed to the pinch seal portions such that the leading ends of the pair of tungsten electrodes project into the discharge space, the method of manufacturing an arc tube comprising the steps of: inserting and disposing a tungsten electrode to portions of a quartz glass tube in which pinch seal portions are formed; and pinch-sealing the portions in which the pinch seal portions are formed in a state where the portions in which the pinch seal portions are formed are heated to 2000°C or higher so that each pinch seal portion is formed.

[0011]

The "tungsten electrode" may be made of pure tungsten or a material to which the other components are added in a case where the main component of the base material of the tungsten electrode is tungsten.

[0012]

The "surfaces of the tungsten electrodes" must include the surfaces of the portions which are pinch-sealed to the pinch seal portions. Therefore, the "surfaces of the tungsten electrodes" are not required to be the overall surfaces.

[0013]

[Operation and Effect of the Invention]

The arc tube according to the present invention and having the above-mentioned structure arranged such that the pair of tungsten electrodes are pinch-sealed to the pinch seal portions

formed on the two sides of the light emission tube of the arc-tube body such that the leading ends of the pair of tungsten electrodes project into the discharge space. Each of the tungsten electrodes has the surfaces exhibiting excellent smoothness such that the average roughness of the surface of each of the tungsten electrodes is 3 mm or smaller.

Therefore, the following operations and effects are obtained.

[0014]

That is, when the tungsten electrodes are pinch-sealed to the pinch seal portions, the two elements are engaged to each other with small pits and projections. Therefore, a problem experienced with the conventional structure that undesirable leaving of great compressive stress in the surfaces of the pinch seal portions in which the pinch seal portions are joined to the tungsten electrodes can be prevented.

[0015]

Therefore, when a crack of the arc-tube body occurs owing to the residual compressive stress during use of the arc tube, the crack is limited to a local portion, which is a region adjacent to the joining surface. That is, the crack is not enlarged to reach the surface of the arc-tube body. As a result, occurrence of a leak between the discharge space and the external space can be prevented.

[0016]

Therefore, the arc tube according to the present invention arranged to prevent a leak occurring due to a crack of the arc-tube body enables its life to be elongated.

[0017]

According to another aspect of the present invention, there is provided a method of manufacturing an arc tube incorporating an arc-tube body which incorporates a light-emission tube arranged to form a discharge space and having pinch seal portions formed on the two sides thereof and which is made of quartz glass; and a pair of tungsten electrodes pinch-sealed to the pinch seal portions such that the leading ends of the pair of tungsten electrodes project into the discharge space, the method of manufacturing an arc tube comprising the steps of: inserting and disposing a tungsten electrode arranged such that the mean surface roughness is

3 mm or smaller into portions of a quartz glass tube in which pinch seal portions are formed; and pinch-sealing the portions in which the pinch seal portions are formed in a state where the portions in which the pinch seal portions are formed are heated to 2000°C or higher so that each pinch seal portion is formed. Therefore, the following operation and effect can be obtained.

[0018]

That is, when the tungsten electrodes are pinch-sealed to the pinch seal portions, the two elements are engaged to each other with small pits and projections. Therefore, a problem experienced with the conventional structure that undesirable leaving of great compressive stress in the surfaces

of the pinch seal portions in which the pinch seal portions are joined to the tungsten electrodes can be prevented.

[0019]

Therefore, when a crack of the arc-tube body occurs owing to the residual compressive stress during use of the arc tube, the crack is limited to a local portion, which is a region adjacent to the joining surface. That is, the crack is not enlarged to reach the surface of the arc-tube body. As a result, occurrence of a leak between the discharge space and the external space can be prevented.

[0020]

The portions in which the pinch seal portions are formed are heated to a high temperature of 2000°C or higher when a pinch sealing operation is performed. Therefore, the bonding strength between the tungsten electrodes and the pinch seal portions can be increased. Therefore, small compressive stress is left in a wide range in a region adjacent to the joining surfaces between the pinch seal portions and the tungsten electrodes.

[0021]

Therefore, the crack of the arc-tube body occurring during use of the arc tube owing to the residual compressive stress is uniformly distributed in the region adjacent to the joining surface. Therefore, extension of the crack to the other portion can effectively be prevented. As a result, occurrence of a leak between the discharge space and the external space can furthermore reliably be prevented.

[0022]

Therefore, employment of the method of manufacturing an arc tube according to the present invention enables the life of the arc tube to furthermore be elongated.

[0023]

[Embodiment of the Invention]

Referring the drawings, an embodiment of the present invention will now be described.

[0024]

Fig. 1 is a side cross sectional view showing a discharge bulb 10 in which an arc tube according to this embodiment is included. Fig. 2 is an enlarged view of the portion II.

[0025]

As shown in Figs. 1 and 2, the discharge bulb 10 is a light source bulb which is mounted on a headlight of a vehicle. The discharge bulb 10 incorporates an arc-tube unit 12 extending in the lengthwise direction and an insulating-plug unit 14 for securing and supporting the rear end of the arc-tube unit 12.

[0026]

The arc-tube unit 12 is constituted by integrally forming an arc tube 16 and a shroud tube 18 surrounding the arc tube 16.

[0027]

The arc tube 16 is constituted by an arc-tube body 20 obtained by machining a quartz glass tube and a pair of front

and rear electrode assemblies 22A and 22B embedded in the arc-tube body 20.

[0028]

The arc-tube body 20 has a light-emission tube 20a formed in the central portion thereof, the light-emission tube 20a being formed into substantially an elliptic shape. Moreover, pinch seal portions 20b1 and 20b2 are formed at the front and rear portions of the light-emission tube 20a. A substantially elliptic-shape discharge space 24 extends in the lengthwise in the light-emission tube 20a. Xenon gas and a metal halide are enclosed in the discharge space 24.

[0029]

The electrode assemblies 22A and 22B have structures that rod-shape tungsten electrodes 26A and 26B and lead wires 28A and 28B are connected and secured to one another through molybdenum foil members 30A and 30B. The electrode assemblies 22A and 22B are pinch-sealed to the arc-tube body 20 in the pinch seal portions 20b1 and 20b2. The molybdenum foil members 30A and 30B are completely embedded in the pinch seal portions 20b1 and 20b2. The tungsten electrodes 26A and 26B project into the discharge space 24 such that their leading ends are opposite to each other in the lengthwise direction.

[0030]

Each of the tungsten electrodes 26A and 26B is constituted such that treated tungsten (tungsten to which thorium oxide is doped by several %) is the base material. Each of outer surfaces 26Aa and 26Ba of the tungsten electrodes 26A and 26B

is subjected to a strong electrolytic polishing process. Thus, the arithmetical mean deviation of profile Ra of each of the outer surfaces 26Aa and 26Ba is 3 mm or smaller (note that the cut-off value  $l_c = 0.8$  mm and the evaluated length  $l_n = 4$  mm). Leading end surfaces 26Ab and 26Bb of the tungsten electrodes 26A and 26B are barrel-polished. The corner R of each of the leading end surfaces 26Ab and 26Bb is about 0.04 mm to about 0.06 mm to obtain a satisfactory discharge characteristic.

[0031]

Fig. 3 is an enlarged view of the portion III shown in Fig. 2 to illustrate a state of the surface with which the tungsten electrode 26B and the pinch seal portion 20b2 are joined to each other after the discharge bulb 10 has been turned on/off several times. Also the surface of joining between the other tungsten electrode 26A and the pinch seal portion 20b1 realizes a similar state.

[0032]

As shown in Fig. 3, the arithmetical mean deviation of profile Ra of the outer surface 26Ba is made to be 3 mm or smaller. Therefore, when the tungsten electrode 26B has been pinch-sealed to the pinch seal portion 20b2, the two elements are engaged to each other with small pits and projections. Hence it follows that undesirable retention of great compressive stress in a region adjacent to the joint surface between the pinch seal portion and the tungsten electrode experienced with the conventional structure can be prevented.

[0033]

Therefore, when a crack of the arc-tube body 20 occurs during use of the arc tube 16 owing to the residual compressive stress, the crack is limited to a local portion, which is the region adjacent to the joining surface. That is, a crack of a type that quartz glass is finely broken occurs in a dashed-line region A shown in Fig. 2. A mirror-shape interface as indicated with an alternate long and two short dashes line is formed in the pinch seal portion 20b2. Therefore, formation of a great crack which reaches the surface of the arc-tube body 20 can be prevented. As a result, occurrence of a leak between the discharge space 24 and the external space can be prevented.

[0034]

Fig. 4 is a diagram showing a pinch-sealing step for pinch-sealing the tungsten electrode 26B to a portion 20b2' of a quartz glass tube 20' in which the pinch seal is formed.

[0035]

Initially, as shown in Fig. 4 (a), a state is realized in which the electrode assembly 22B is inserted into a predetermined position from a position lower than the quartz glass tube 20' which is formed into the arc-tube body 20 having the light-emission tube 20a. Then, the lower end of the portion 20b2' in which the pinch seal is formed is heated by a burner 2. Thus, as shown in Fig. 4 (b), a temporal pincher 4 is operated to temporarily pinch-seal the electrode assembly 22B to the foregoing lower end.

[0036]

Then, as shown in Fig. 4 (c), the portion 20b2' in which the pinch seal is formed is heated to 2000°C or higher (preferably 2100°C to 2200°C) by a burner 6. In the foregoing state, as shown in Fig. 4 (d), a main pinch-sealing process is performed so that the electrode assembly 22B is pinch-sealed to the portion 20b2' in which the pinch seal is formed by operating a main pincher 8. Thus, the pinch seal portion 20b2 is formed.

[0037]

Thus, the portion 20b2' in which the pinch seal is formed is heated at a high temperature of 2000°C or higher when the main pinch sealing of the portion 20b2' in which the pinch seal is formed is performed. Therefore, the bonding strength between the tungsten electrode 26B and the pinch seal portion 20b2 of the electrode assembly 22B can be increased. As a result, small compressive stress is uniformly left in a wide range in the region adjacent to the joint surface between the pinch seal portion 20b2 and the tungsten electrode 26B.

[0038]

Therefore, the cracks of the arc-tube body 20 occurring during use of the arc tube 16 owing to the residual compressive stress is substantially uniformly distributed in the region adjacent to the joint surface. The above-mentioned mirror-shape interface can easily be formed. Moreover, extension of the crack to the other portion can effectively be prevented. Therefore, occurrence of a leak between the

discharge space 24 and the external space can furthermore reliably be prevented.

[0039]

Table 1 shows the relationship between the surface roughness (the arithmetical mean deviation of profile Ra) of the outer surface of the tungsten electrode and the life (mean life Tc and initial defect generation time B3) of the arc tube. Table 2 shows the relationship between the temperature t to which the portion in which the pinch seal is formed when the main pinch sealing process is performed is heated and the life of the arc tube (mean life Tc and initial defect generation time B3).

[0040]

TECHNOLOGY CENTER 2800

NOV 18 2003

RECEIVED

[0042]

As can be understood from Table 1, the above-mentioned setting that the arithmetical mean deviation of profile Ra is 3 mm or smaller enables the mean life to be about 2000 hours or longer. As can be understood from Table 2, the temperature  $t$  to which the portion in which the pinch seal portion is formed is made to be 2000°C or higher when the main pinch sealing process is performed. Thus, a mean life of about 2000 hours or longer can be realized.

[0043]

Note that the mean life  $T_c$  shown in the two tables is time at which 63.2 % of all of the samples encounters problems (the arc tube cannot be turned on). Initial defect generation time  $B_3$  is time at which 3 % of all of the samples encounters problems (the arc tube cannot be turned on). When also the mean life  $T_c$  is used, dispersion of the life can be detected.

[0044]

As described above, the arc tube 16 according to the embodiment incorporates the tungsten electrodes 26A and 26B pinch-sealed to the pinch seal portions 20b1 and 20b2 on the two sides of the light-emission tube 20a of the arc-tube body 20. The tungsten electrodes 26A and 26B exhibit excellent surface smoothness such that the arithmetical mean deviation of profile Ra of each of the outer surfaces 26Aa and 26Ba is 3 mm or smaller. When the tungsten electrodes 26A and 26B have been pinch-sealed to the pinch seal portions 20b1 and 20b2, the two elements are engaged to each other with small pits

and projections. As a result, retention of great compressive stress in the region adjacent to the joint surface between the pinch seal portions 20b1 and 20b2 and the tungsten electrodes 26A and 26B can be prevented.

[0045]

Therefore, when a crack of the arc-tube body 20 occurs during use of the arc tube 16 owing to the residual compressive stress, the crack is limited to a local portion which is the region adjacent to the joint surface. That is, the crack is not enlarged to reach the surface of the arc-tube body 20. As a result, occurrence of a leak between the discharge space 24 and the external space can be prevented. Hence it follows that the life of the arc tube 16 can be elongated.

[0046]

In this embodiment, the pinch sealing process is performed in a state where the portion 20b2' of the quartz glass tube 20' in which the pinch seal is formed is heated to 2000°C or higher so that the pinch seal portion 20b2 is formed. Therefore, the bonding strength between the tungsten electrode 26B and the pinch seal portion 20b2 is increased. As a result, small compressive stress is substantially uniformly left in a wide range in a region adjacent to the joint surface between the pinch seal portion 20b2 and the tungsten electrode 26B. The foregoing face also applies to the region adjacent to the joint surface between the pinch seal portion 20b1 and the tungsten electrode 26A.

[0047]

Therefore, the crack of the arc-tube body 20 occurring during use of the arc tube 16 owing to the residual compressive stress is substantially uniformly distributed in the region adjacent to the joint surface. Therefore, extension of the crack to the other portion can effectively be prevented. Thus, occurrence of a leak between the discharge space 24 and the external space can furthermore reliably be prevented. Hence it follows that the life of the arc tube 16 can be elongated.

[0048]

In this embodiment, the lower end of the portion 20b2' in which the pinch seal is formed is heated (refer to Fig. 4 (a)) by the burner 2 prior to performing the temporal pinch sealing operation shown in Fig. 4 (b). The foregoing heating process does not directly concern the bonding strength between the tungsten electrode 26B and the pinch seal portion 20b2. Therefore, no description has been made about the temperature to which the lower end must be heated. As a matter of course, the temperature may be 2000°C or higher similarly to the main pinch sealing process.

[0049]

In this embodiment, the arithmetical mean deviation of profile Ra of the outer surfaces 26Aa and 26Ba of the tungsten electrodes 26A and 26B is made to be 3 mm or smaller. Moreover, the portion 20b2' in which the pinch seal is formed is heated to 2000°C or higher when the main pinch sealing process is performed. As can be understood from Tables 1 and 2, it is preferable that the arithmetical mean deviation of profile

Ra is 2 mm or smaller. Moreover, it is preferable that the temperature is made to be 2100°C or higher. In the foregoing case, the life of the arc tube 16 can furthermore be elongated.  
[0050]

In this embodiment, the arc tube is the arc tube 16 for a discharge bulb 10 which is mounted on a headlight of a vehicle. As a matter of course, the arc tube according to this embodiment may be applied to another purpose.

[Name of Document] Abstract

[Abstract]

[Problem]

It is an object to provide an arc tube which is capable of elongating the life thereof by preventing occurrence of a leak caused from a crack of an arc-tube body.

[Means For Solution]

The mean surface roughness of each of outer surfaces 26Aa and 26Ba of tungsten electrodes 26A and 26B pinch-sealed to pinch seal portions 20b1 and 20b2 on the two sides of a light-emission tube 20a of an arc-tube body 20 is set to be 3 mm or smaller. Thus, the state of pinch-sealing of the tungsten electrodes 26A and 26B to the pinch seal portions 20b1 and 20b2 is brought to a state in which the two elements are engaged with small pits and projections. Therefore, great compressive stress is not left in the region adjacent to the joint surface between the pinch seal portions 20b1 and 20b2 and the tungsten electrodes 26A and 26B as distinct from the conventional structure. In a case where a crack of the arc-tube body 20 is formed owing to the residual compressive stress, the crack is limited to a local portion which is the region adjacent to the joint surface. As a result, the crack is not enlarged to reach the surface of the arc-tube body 20.
